Calcium
What is it and why is it important?
Calcium is an essential mineral. Most of us know that calcium is needed for bone health, but it has other functions in the body too!

Introduction

Calcium is an essential mineral. Most of us know that calcium is needed for bone health, but it has other functions in the body too!
Along with bone health, calcium has many other roles in the body, it:

- Supports normal digestive enzymes
- Supports normal muscle function
- Has a role in the process of cell division & specialisation
- Contributes to normal blood clotting
- Supports normal energy-yielding metabolism (the release of energy from foods)
- Contributes to normal neurotransmission (the delivery of messages between nerve cells)
- Supports normal function of digestive enzymes
Importance of Calcium for bone health throughout life

**TEENAGERS**
Around 90% of the adult skeleton is formed by the age of 18. 
Teenage girls need 800mg calcium a day and teenage boys 1000mg a day.

**MENOPAUSE**
An extra 500mg calcium* is recommended to help reduce loss of bone mineral in post-menopausal women.

**PREGNANCY & BREASTFEEDING**
There is no increase in calcium requirements during pregnancy. Breastfeeding women need an extra 550mg calcium a day.

**ADULTS**
Bones continue to strengthen until our mid-thirties.

**CHILDREN**
Calcium is needed for growth and development of bone in children. Physical activity is important too!

*Calcium helps to reduce loss of bone mineral in post-menopausal women. Low bone mineral density is a risk factor for osteoporosis.
Lifestyle and bone health

Like muscles, our bones need regular exercise to keep them strong.

Weight-bearing activities, where our feet and legs support our weight, are particularly good for bones. These include running, skipping and dancing, even brisk walking. Adults should aim for at least 2½ hours per week, with muscle strengthening activities 2 days a week.

Not smoking and limiting alcohol intake is also good for bone health.

Dairy foods and calcium

Including milk, cheese and yogurt in the diet is a great way to help meet our calcium needs.

The table on page 11 shows the recommended calcium intakes for different ages, as well as the portion sizes that can help meet these needs.

Calcium isn’t the only bone-friendly nutrient that milk, cheese and yogurt provide! They also contain protein and phosphorus, both of which support the maintenance of normal bones.
A daily supplement of 10μg vitamin D is recommended all year round for:

- all pregnant and breastfeeding women
- babies and young children
- those aged 65 years and over
- people with darker skin
- people who spend lots of time indoors.

For more information on vitamin D, visit The British Dietetic Association's Food Fact Sheet on Vitamin D (link on back page)

* RNI, Reference Nutrient Intake, is a figure set by the Department of Health for the amount of a nutrient that is enough to meet the dietary needs of most people (97.5%).

---

*Extra 500 mg during breastfeeding*
A balanced and varied diet should provide enough calcium to meet our requirements. If you take a calcium supplement, make sure your total intake doesn’t exceed 1500mg/day as this may cause stomach pain and diarrhoea.

Children under five years old shouldn’t be given whole nuts because of the risk of choking. Those with a medically diagnosed allergy to any of the pictured foods should avoid them.
